With capacitors in series, the charging current (i_C) flowing through the capacitors is THE SAME for all capacitors as it only has one path to follow. Then, Capacitors in Series all have the same current flowing through them as $i_T = i_1 = i_2 = i_3$ etc. Therefore each capacitor will store the same amount of electrical charge, Q on its plates regardless of its capacitance.

The Parallel Combination of Capacitors. A parallel combination of three capacitors, with one plate of each capacitor connected to one side of the circuit and the other plate connected to the other side, is illustrated in Figure 8.12(a). Canceling the charge Q , we obtain an expression containing the equivalent capacitance, C_S , of three capacitors connected in series: $\frac{1}{C_S} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}$. $\frac{1}{C_S} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}$. This expression can be generalized to any number of capacitors in a series network.

Energy storage in capacitors. This formula shown below explains how the energy stored in a capacitor is proportional to the square of the voltage across it and the capacitance of the capacitor. It's a crucial concept in understanding how capacitors store and release energy in electronic circuits. $E = 0.5 C V^2$. Where: E is the energy stored in ...

Capacitors can store energy when a battery or voltage source is connected. A parallel plate capacitor is made up of 2 conducting plates (electrodes), separated by an insulating material (dielectric). Also, because capacitors store the energy of the electrons in the form of an electrical charge on the plates the larger the plates and/or smaller their separation the greater will be the charge that the capacitor holds for any given voltage across its plates.

A charged capacitor stores energy in the electrical field between its plates. As the capacitor is being charged, the electrical field builds up. When a charged capacitor is disconnected from a battery, its energy remains in the field in the space between its plates.
