Thermodynamics is a science that deals with storage, transformation and transfer of energy. It is fundamental to the topics of thermal energy storage, which consists of a collection of technologies that store thermal (heat or cold) energy and use the stored energy directly or indirectly through energy-conversion processes when needed.

The energy (U_C) stored in a capacitor is electrostatic potential energy and is thus related to the charge Q and voltage V between the capacitor plates. A charged capacitor stores energy in the electrical field between its plates. As the capacitor is being charged, the electrical field builds up.

Energy stored in a capacitor is electrical potential energy, and it is thus related to the charge Q and voltage V on the capacitor. We must be careful when applying the equation for electrical potential energy $DPE = qDV$ to a capacitor. Remember that DPE is the potential energy of a charge q going through a voltage DV .

Heat Capacity. We now introduce two concepts useful in describing heat flow and temperature change. The heat capacity ((C)) of a body of matter is the quantity of heat ((q)) it absorbs or releases when it experiences a temperature change ((DT)) of 1 degree Celsius (or equivalently, 1 kelvin) [$C = \frac{q}{DT}$ label{12.3.1}] Heat capacity is determined by both ...

Since batteries need to store energy for long periods of time, using materials that have a greater gravimetric energy storage capacity is essential. The storage capacity of the battery is also expressed in watt hours or Wh. If V is the battery voltage, then the energy storage capacity of the battery can be $Ah \times V = \text{watt hour}$.
