As strain has no units, the units for Young's Modulus are the same as the units for stress - Newtons per metre squared (Nm^{-2}) or in SI units Pascals (Pa).. **IMPORTANT:** Young's Modulus only applies when an object is undergoing elastic deformation NOT plastic deformation. The value tells us how stiff a material is - the greater the value, the stiffer the material.

length of the cable). This use of the word elastic must not be confused with the use of the term as in "elastic band," where "elastic" is taken to mean highly extensible. Young's modulus is a measure of stiffness in simple extension or compression. There are ways of deforming a material that have different effects on the interatomic

It's measured in meters and is dimensionless. You can calculate the strain using a formula. Young's modulus formula. Young's modulus, or elastic modulus, is a measure of how stretchy and stiff materials are. It's calculated by dividing stress by strain. The units of Young's modulus are the same as stress, which is measured in N/m^2 ; or Pa.

Young's modulus, also known as longitudinal modulus of elasticity or elastic modulus, is a mechanical property of materials that describes their stiffness or resistance to elastic deformation when an external force is applied.

Young's modulus compares tensile or compressive stress to axial strain. The formula for Young's modulus is: $E = \sigma / \epsilon = (F/A) / (\Delta L/L_0) = FL_0 / A\Delta L = mgL_0 / \rho A \Delta L$ Where: While the SI unit for Young's modulus is the pascal (Pa). However, the pascal is a small unit of pressure, so megapascals (MPa) and gigapascals (GPa) are more common.

Therefore, the Young's Modulus (E) formula is: $E = \text{stress} / \text{strain}$ Materials with a high Young's Modulus, like steel or diamond, are stiff and resistant to deformation, meaning they can withstand significant loads without stretching or compressing much.

A low Young's modulus value means a solid is elastic. A high Young's modulus value means a solid is inelastic or stiff. The behavior of a rubber band illustrates Young's modulus. A rubber band stretches, but when you release the force it returns to its original shape and is not deformed.

Elastic modulus, also known as the modulus of elasticity, is a fundamental material property that measures a substance's ability to resist deformation under stress, defined by the ratio of stress (force per unit area) to strain (proportional deformation) in a material. It is typically expressed in Pascals (Pa) and is crucial in engineering and physics for determining how much a material will ...

The storage modulus is a measure of how much energy must be put into the sample in order to distort it. The difference between the loading and unloading curves is called the loss modulus, E'' . It measures energy lost during that cycling strain. Why would energy be lost in this experiment? In a polymer, it has to do chiefly with chain flow.
