There are two basic Thermal Energy Storage (TES) Strategies, latent heat systems and sensible heat systems. Stratification is used within the tank as a strategy for thermal layering of the stored water. Colder water is denser and will settle toward the bottom of the tank, while the warmer water will naturally seek to rise to the top.

The smaller the tank, the more often you will need to refill it, but on the other hand, it is the most compact of the three sizes. The 10-lb tank is going to be the middle of the three and is probably the happy-medium of pressure capacity and physical size as well.

Tank thermal energy storage (TTES) are often made from concrete and with a thin plate welded-steel liner inside. The type has primarily been implemented in Germany in solar district heating systems with 50% or more solar fraction. Storage sizes have been up to 12,000 m³ (Figure 9.23). Figure 9.23.
