The battery also does not have low-voltage cutoff - there are no transistors in the battery that can cut the power. Instead, low-voltage cutoff is done by the battery detecting low voltage and signalling the tool to stop. The battery monitors each of the 5 sets of cells individually and cuts off whenever any of them drop below the minimum voltage.

This is ...

A low-voltage, battery-based energy storage system (ESS) stores electrical energy to be used as a power source in the event of a power outage, and as an alternative to purchasing energy from a utility company. Nominal Voltage. The nominal voltage of LiFePO₄ batteries is usually 3.2V per cell, resulting in a typical 12.8V for a 4-cell battery pack. **Low Voltage Cutoff Explained.** What is Low Voltage Cutoff? Low voltage cutoff is the predetermined voltage threshold below which a ...

The battery's cut-off voltage is determined by the manufacturer, so that consumers can achieve the maximum capacity of their batteries. The cut-off voltage depends on the type of battery under use and differs from one battery to the other. For example: a) NiCd or NiMH battery has the cut-off voltage of 1.0 V b) Alkaline battery - 0.9 V

With high energy density, low self-discharge rate and long cycle life, lithium-ion batteries are widely used in cell phones, laptops, electric vehicles and energy storage systems. The voltage of a lithium-ion battery is the potential difference between the battery terminals during charging and discharging.

The 50% is 50% of the battery stored energy, not a function of either load or voltage. This is why you cannot "set the LCBO for 50%" - you have to get that notion out of your mind. The trouble is you are trying to approximate 50% energy with a voltage reading. If you really want to know, put on your slippers and go check the specific gravity.
