

The storage modulus" change with frequency depends on the transitions involved. Above the T g, the storage modulus tends to be fairly flat with a slight increase with increasing frequency as it is on the rubbery plateau. The change in the region of a transition is greater.

The above equation is rewritten for shear modulus as, (8) " $G^* = G'' + iG$  where G? is the storage modulus and G?? is the loss modulus. The phase angle d is given by (9) " " tan G G d= The storage modulus is often times associated with "stiffness" of a material and is related to the Young's modulus, E. As the curve in Figure 17 shows, the modulus also varies as a function of the frequency. A material exhibits more elastic-like behavior as the testing frequency increases and the storage modulus tends to slope upward toward higher frequency. The storage modulus' change with frequency depends on the transitions involved.

Dynamic Mechanical Analysis (DMA) is a characterization method that can be used to study the behavior of materials under various conditions, such as temperature, frequency, time, etc. The test methodology of DMA, which aims mainly at the examination of solids, has its roots in rheology (see also "Basics of rheology"), a scientific discipline that studies the viscoelastic properties of ...

the loss modulus, see Figure 2. The storage modulus, either E" or G", is the measure of the sample"s elastic behavior. The ratio of the loss to the storage is the tan delta and is often called damping. It is a measure of the energy dissipation of a material. Q How does the storage modulus in a DMA run compare to Young"s modulus?

If one can generate a modulus scan over a wide enough frequency range (Fig. 18), the plot of storage modulus versus frequency appears like the reverse of a temperature scan. The same time-temperature equivalence discussed above also applies to modulus, as well as compliance, tan delta, and other properties.

where G? is the shear storage modulus of the plateau region at a specific temperature, r is the polymer density, and M e is the molecular weight between entanglements. In practice, the relative modulus of the plateau region shows the relative changes in M e or the number of cross-links compared to a standard material.

The storage modulus G ? from the data and the SGR model match each other well even up to  $o / G 0 \sim 1$  where we cannot expect good agreement.
