The tourbillon was invented to average poise errors by rotating the escapement What he came up with was a device that encapsulated the entire escapement, rotating it so that each part of the balance wheel took its turn to work hardest, therefore evening out the effects of gravity. He named it "whirlwind"--which, in French, is "tourbillon".

Before we talk about what a tourbillon is, let's address why it was needed in the first place. The balance wheel, the beating heart of a mechanical movement, is subjected to the constant force of gravity as it swings backwards and forwards. Imagine a weight on the end of a rope. You're holding the other end of that rope.

In a tourbillon, the escapement and balance wheel are mounted in a rotating cage, with the goal of eliminating errors of poise in the balance giving a uniform weight. Tourbillons are still included in some modern wristwatches, where the mechanism is usually exposed on the watch's face to showcase it.

Tourbillon cages may take on a variety of styles, but like a balance wheel, should have high inertia while being as light as possible. Now that the cage is rotating, how is power delivered to the balance wheel? The answer is simpler than you may think: under the cage and fixed to the movement's baseplate is a stationary fourth wheel.

The movement is designed with a central balance wheel. The swing frequency is 28,800 times per hour which makes the time become precise. The tourbillon is placed at 12 o'clock and the logo is marked on the tourbillon. It is made specially without affecting the stability of the watch movement. It is also equipped with a 60-hour power reserve.
